

SSH Remote Echo

Description

Bob is testing a secure remote communication system where he wants to verify if his custom SSH command is constructed and handled properly. The SSH command is supposed to send a remote message:

```
ssh bob@example.com "echo Hello bob from example.com"
```

However, instead of actually connecting via SSH, your task is to simulate the behavior by writing a program that constructs the command and processes a mocked return value.

You are to write a function that returns the standard error output (as a string) from running the simulated SSH command. The standard error output should be the message:

```
Hello bob from example.com
```

Input

There is no input.

Output (with unit test)

```
test attribute passed: ssh is equal to ssh
test attribute passed: bob is equal to bob
test attribute passed: example.com is equal to example.com
test attribute passed: Hello bob from example.com
is equal to Hello bob from example.com
```
