XML—RPC Client

Description
You are tasked with implementing a client that connects to an
XML—RPC server to perform mathematical operations. The server
provides two functions: calculating the factorial of a number
and checking if a number is prime. Your client should connect
to this server, call these functions, and handle the results
appropriately.

Implementation
You need to implement a client that connects to an XML—RPC
server running on http://localhost:8000/ and performs the
following operations:
— Call the factorial function with the input 5 and print the
result.
— Call the is_prime function with the inputs 29 and 30, and
print the results for each call.

Output (with unit test)

Factorial of 5 is 120
Is 29 a prime number? True
Is 30 a prime number? False
test attribute passed: 120 is equal to 120
test attribute passed: True is equal to True
test attribute passed: False is equal to False
